Soil microbial diversity has been investigated in the past 30 years, starting with the

works of Tillmanns and Church. Here we review current knowledge about soil microbial communities and their properties, focusing on recently published research. Using two-photon excitation microscopy in combination with fluorescence in situ hybridization we have demonstrated that the transition zone of the upper soil horizon contains two microbial populations: one predominantly composed of bacteria and the other of fungi. Diverse analyses revealed that the diversity of microorganisms was higher in the topsoil than in the subsoil, which may be explained by two processes: one is an increase of specific taxa and the other is an increase of their abundance in the topsoil. The density of microorganisms was highest in the zone of maximum plant activity, and the number of microorganisms increased exponentially with increasing soil temperature. In the subsoil, Actinobacteria and Bacteroidetes were more abundant than in the topsoil, whereas in the topsoil, most of the bacteria were Nitrospira and some of them are capable of N-fixation. Future studies will have to address the response of soil microbial communities to changes in the climatic conditions. The line between the religious and the secular world is blurring, as the intersection of faith

and progressive politics continues to thrive. This interfaith series features Hindu f988f36e3a
